

# *Classes and Objects in C++*

Shahram Rahatlou

*Computing Methods in Physics*

<http://www.roma1.infn.it/people/rahatlou/cmp/>

*Anno Accademico 2018/19*

SAPIENZA  
UNIVERSITÀ DI ROMA

# Today's Lecture

- **Classes**

- data members and member functions

- **Constructors**

- Special member functions

- **private and public members**

- **Helper and utility methods**

- setters
- getters
- accessors

# Classes in C++

- A class is a set of data and functions that define the characteristics and behavior of an object
  - Characteristics also known as attributes
  - Behavior is what an object can do and is referred to also as its interface

Interface  
or  
Member Functions

Data members or  
attributes

```
class Result {  
    public:  
  
    // constructors  
    Result() { }  
    Result(const double& mean, const double& stdDev) {  
        mean_ = mean;  
        stdDev_ = stdDev;  
    }  
  
    // accessors  
    double getMean() { return mean_; };  
    double getStdDev() { return stdDev_; };  
  
    private:  
    double mean_;  
    double stdDev_;  
};
```

Don't's forget ; at the end of definition!

# Data Members (Attributes)

```
#include <iostream>
using namespace std;

class Datum {
    double value_;
    double error_;
};
```

- Data defined in the scope of a class are called data members of that class
- Data members are defined in the class and can be used by all member functions
- Contain the actual data that characterise the content of the class
- Can be public or private
  - public data members are generally bad and symptom of bad design
  - More on this topic later in the course

# Interface: Member Functions

- Member functions are methods defined inside the scope of a class
  - Have access to all data members

`name_` is a datamember

No declaration of `name_` in member functions!

`name` is a local variable only within `setName()`

```
// Student
#include <iostream>
#include <string>
using namespace std;

class Student {
public:
    // default constructor
    Student() { name_ = ""; }

    // another constructor
    Student(const string& name) { name_ = name; }

    // getter method: access to info from the class
    string name() { return name_; }

    // setter: set attribute of object
    void setName(const string& name) { name_ = name; }

    // utility method
    void print() {
        cout << "My name is: " << name_ << endl;
    }

private:
    string name_; // data member
};
```

# Arguments of Member Functions

- All C++ rules discussed so far hold
- You can pass variables by value, pointer, or reference
- You can use the constant qualifier to protect input data and restrict the capabilities of the methods
  - This has implications on declaration of methods using constants
  - We will discuss constant methods and data members next week
- Member functions can return any type
  - Exceptions! Constructors and Destructor
    - Have no return type
    - More on this later

# Access specifiers **public** and **private**

- Public functions and data members are available to anyone
- Private members and methods are available ONLY to other member functions

```
1 #include <iostream>
2 using std::cout;
3 using std::endl;
4
5 class Datum {
6     public:
7         Datum() { }
8         Datum(double val, double error) {
9             value_ = val;
10            error_ = error;
11        }
12
13        double value() { return value_; }
14        double error() { return error_; }
15
16        void setValue(double value) { value_ = value; }
17        void setError(double error) { error_ = error; }
18
19        double value_; // public data member!!!
20
21    private:
22        double error_; // private data member
23 };;
```

Access elements of an object through member selection operator “.”

```
25 int main() {
26
27     Datum d1(1.1223,0.23);
28
29     cout << "d1.value(): " << d1.value() ^
30         << " d1.error(): " << d1.error()
31         << endl;
32
33
34     cout << "d1.value_: " << d1.value_
35         << " d1.error_: " << d1.error_
36         << endl;
37
38     return 0;
39 }
```

Accessing private members  
is a compilation error!

```
$ g++ -o class1 class1.cc
class1.cc: In function `int main()':
class1.cc:22: error: `double Datum::error_' is private
class1.cc:35: error: within this context
```

# private members

```
#include <iostream>
using namespace std;

class Datum {
public:
    Datum(double val, double error) {
        value_ = val;
        error_ = error;
    }

    double value() { return value_; }
    double error() { return error_; }

    void setValue(double value)
    { value_ = value; }
    void setError(double error)
    { error_ = error; }

    void print() {
        cout << "datum: " << value_
              << " +/- " << error_
              << endl;
    }

private:
    double value_; // private data member!!!
    double error_; // private data member
};
```

```
int main() {

    Datum d1(1.1223,0.23);
    // setter with no return value
    d1.setValue( 8.563 );

    // getter to access private data
    double x = d1.value();

    cout << "d1.value(): " << d1.value()
          << " d1.error(): " << d1.error()
          << endl;

    d1.print();

    return 0;
}
```

```
$ g++ -o class2 class2.cc
$ ./class2
d1.value(): 8.563 d1.error(): 0.23
datum: 8.563 +/- 0.23
```

# private methods

- Can be used only inside other methods but not from outside

```
1 // class3.cc
2 #include <iostream>
3 using namespace std;
4
5 class Datum {
6     public:
7         Datum() { reset(); } // reset data members
8
9         double value() { return value_; }
10        double error() { return error_; }
11
12        void setValue(double value) { value_ = value; }
13        void setError(double error) { error_ = error; }
14
15        void print() {
16            cout << "datum: " << value_ << " +/- "
17                << error_ << endl;
18        }
19    private:
20        void reset() {
21            value_ = 0.0;
22            error_ = 0.0;
23        }
24
25        double value_;
26        double error_;
27 };
```

```
int main() {

    Datum d1;
    d1.setValue( 8.563 );
    d1.print();

    return 0;
}
```

```
$ g++ -o class3 class3.cc
$ ./class3
datum: 8.563 +/- 0
```

```
30 int main() {
31
32     Datum d1;
33     d1.setValue( 8.563 );
34     d1.print();
35     d1.reset();
36
37     return 0;
38 }
```

```
$ g++ -o class4 class4.cc
class4.cc: In function `int main()':
class4.cc:20: error: `void Datum::reset()' is private
class4.cc:35: error: within this context
```

# Hiding Implementation from Users/Clients

- How to decide what to make public or private?
- Principle of Least Privilege
  - elements of a class, data or functions, must be private unless proven to be needed as public!
- Users should rely solely on the interface of a class
- They should never use the internal details of the class
- ***That's why having public data members is a VERY bad idea!***
  - name and characteristics of data members can change
  - Functionalities and methods remain the same
  - You must be able to change internal structure of the class without affecting the clients!

# Bad Example of Public Data Members

```
class Datum {
public:
    Datum(double val, double error) {
        value_ = val;
        error_ = error;
    }

    double value() { return value_; }
    double error() { return error_; }

    void setValue(double value) { value_ = value; }
    void setError(double error) { error_ = error; }

    void print() {
        cout << "datum: " << value_ << " +/- " << error_ << endl;
    }

//private:      // all data are public!
    double value_;
    double error_;
};
```

```
int main() {

    Datum d1(1.1223,0.23);
    double x = d1.value();
    double y = d1.error_;
    cout << "x: " << x << "\t y: " << y << endl;

    return 0;
}
```

application uses directly  
the data member!

```
$ g++ -o class6 class6.cc
$ ./class6
x: 1.1223          y: 0.23
```

# Bad Example of Public Data Members

Same Application as before

Change the names of data members

No change of functionality so no one should be affected!

```
class Datum {
public:
    Datum(double val, double error) {
        val_ = val;
        err_ = error;
    }

    double value() { return val_; }
    double error() { return err_; }

    void setValue(double value) { val_ = value; }
    void setError(double error) { err_ = error; }

    void print() {
        cout << "datum: " << val_ << " +/- " << err_ << endl;
    }

//private:          // alla data are public!
    double val_;    // value_ → val_
    double err_;    // error_ → err_
};
```

```
28 int main() {
29
30     Datum d1(1.1223,0.23);
31     double x = d1.value();
32     double y = d1.error_;
33
34     cout << "x: " << x << "\t y: " << y << endl;
35
36     return 0;
37 }
```

Our application is now broken!

But Datum has not changed its behavior!

Bad programming!

Only use the interface of an object not its internal data!

Private data members prevent this

```
$ g++ -o class7 class7.cc
class7.cc: In function `int main()':
class7.cc:32: error: 'class Datum' has no member named 'error_'
```

# Constructors

```
class Datum {  
    public:  
        Datum() { }  
        Datum(double val, double error) {  
            value_ = val;  
            error_ = error;  
        }  
  
    private:  
        double value_; // public data member!!!  
        double error_; // private data member  
};
```

- Special member functions
  - Required by C++ to create a new object
  - MUST have the same name of the class
  - Used to initialize data members of an instance of the class
  - Can accept any number of arguments
    - Same rules as any other C++ function applies
- Constructors have no return type!
- There can be several constructors for a class
  - Different ways to declare and an object of a given type

# Different Types of Constructors

- Default constructor
  - Has no argument
  - On most machines the default values for data members are assigned
- Copy Constructor
  - Make a new object from an existing one
- Regular constructor
  - Provide sufficient arguments to initialize data members

```
class Datum {  
    public:  
        Datum() { }  
  
        Datum(double x, double y) {  
            value_ = x;  
            error_ = y;  
        }  
  
        Datum(const Datum& datum) {  
            value_ = datum.value_;  
            error_ = datum.error_;  
        }  
  
    private:  
        double value_;  
        double error_;  
};
```

# Using Constructors

```
// class5.cc
#include <iostream>
using namespace std;

class Datum {
public:
    Datum() { }

    Datum(double x, double y) {
        value_ = x;
        error_ = y;
    }

    Datum(const Datum& datum) {
        value_ = datum.value_;
        error_ = datum.error_;
    }

    void print() {
        cout << "datum: " << value_
              << " +/- " << error_
              << endl;
    }

private:
    double value_;
    double error_;
};
```

```
int main() {

    Datum d1;
    d1.print();

    Datum d2(0.23,0.212);
    d2.print();

    Datum d3( d2 );
    d3.print();

    return 0;
}
```

```
$ g++ -o class5 class5.cc
$ ./class5
datum: NaN +/- 8.48798e-314
datum: 0.23 +/- 0.212
datum: 0.23 +/- 0.212
```

# Default Constructors on Different Architectures
